

internal.jrdltd.co.uk: what Steve does

A page of tiles that sends staff to askSOPHIE, askTIMELY and the rest. It is plain HTML served off the disk. No Node, no service, no database, no sign-in of its own, nothing to back up: if the folder is there, the page works.

Internal only, the same as askSOPHIE.

1. DNS

Create `internal.jrdltd.co.uk` pointing at the server, on the internal network only. It does not need to resolve from the internet and should not.

2. Certificate

The same one askSOPHIE uses if it is a wildcard for `*.jrdltd.co.uk`; otherwise a certificate for this name.

3. The folder

On the server, next to the asksophie folder:

```
git clone --branch live https://TOKEN@github.com/Transmission-Dynamics/iw-internal.git internal
```

with the same iw-server token askSOPHIE now uses in place of TOKEN.

4. Apache

A vhost on 443 for `internal.jrdltd.co.uk` with the certificate, and:

```
DocumentRoot "C:/path/to/internal/public"  
DirectoryIndex index.html
```

Keep the internal-IP Require ip rule that the askSOPHIE vhost has, so it answers on the work network and the VPN and nowhere else. There is no proxy and no port to open: Apache reads the file itself.

Reload Apache.

5. Keeping it up to date

Copy the scheduled task that runs askSOPHIE's `update.bat` every minute and point the copy at this folder's `update.bat`. It pulls the `live` branch and stops. There is no service to restart, so a deploy is invisible: the next person to load the page gets the new one.

If a task every minute is more than this deserves, every fifteen is plenty – the page changes a few times a year.

6. Tell Murven

That the hostname resolves and the page loads over HTTPS from a desk.

Rollback

```
cd internal  
git reset --hard <the previous commit>
```

and the page is back. Nothing else holds any state.
